The choice of candidate genes is based on the current knowledge of human pathophysiology, pharmacology, and cancer biology. The hypothesis is that genetic variations in genes that play an important role in the pharmacokinetics or pharmacodynamics of a drug would likely affect the drug's efficacy and/or toxicity.

Pharmacogenomics is the study of how a patient's genome can influence how they respond to medicines. Variants in an individual's genome can increase the functioning of medicines or make them ineffective. They can also help predict which patients will suffer from side-effects – from the merely unpleasant to potentially life-threatening.

Genomics and pharmacogenomics of pediatric acute lymphoblastic leukemia. Acute lymphoblastic leukaemia (ALL) is a prevalent form of pediatric cancer that accounts for 70-80% of all leukemias. Genome-based analysis, exome sequencing, transcriptomics and proteomics have provided insight into genetic classification of ALL and helped identify novel subtypes of the disease.

Cancer pharmacogenomics is the study of how variances in the genome influences an individual's response to different cancer drug treatments. It is a subset of the broader field of pharmacogenomics, which is the area of study aimed at understanding how genetic variants influence drug efficacy and toxicity. Cancer is a genetic disease where changes to genes can cause cells to grow and divide out of control. Each cancer can have a unique combination of genetic mutations, and even cells within ...

Abstract. The development of clinical practice recommendations or guidelines for the clinical use of pharmacogenomics data is an essential issue for improving drug therapy, particularly for drugs with high toxicity and/or narrow therapeutic index such as anticancer drugs. Although pharmacogenomic-based recommendations have been formulated for over 40 anticancer drugs, the number of clinical practice guidelines available is very low.

A place may also exist in forensic pathology, in which pharmacogenomics can be used to determine the cause of death in drug-related deaths where no findings emerge using autopsy. [citation needed] In cancer treatment, pharmacogenomics tests are used to identify which patients are most likely to respond to certain cancer drugs. In behavioral health, pharmacogenomic tests provide tools for physicians and care givers to better manage medication selection and side effect amelioration.

elimination of the different glucuronidated compounds. Seventeen human UGT transcripts have been identified thus far, and the UGT proteins are differentially expressed in a wide-range of human tissues. Genetic variants have been identified in coding and non-coding sequences of several UGT genes, and similar observations should be anticipated for all UGTs. As glucuronidation plays a critical ...
