A pluggable authentication module ( PAM) is a mechanism to integrate multiple low-level authentication schemes into a high-level application programming interface

# Read Book Pluggable Authentication Modules

(API). It allows programs that rely on authentication to be written independent of the underlying authentication scheme. PAM was first proposed by Sun Microsystems in an Open Software Foundation Request for Comments (RFC) 86.0 dated October 1995.

The pluggable authentication module (PAM) framework provides system administrators with the ability to incorporate

# Read Book Pluggable Authentication Modules

multiple authentication mechanisms into an existing system through the use of pluggable modules. Applications enabled to make use of PAM can be plugged-in to new technologies without modifying the existing applications. This flexibility allows administrators to do the following:

Pluggable Authentication Modules (PAM)

# Read Book Pluggable Authentication Modules

Because there are so many ways to authenticate users, it ' s convenient to have a unified approach to authentication that can handle multiple authentication systems for different needs. The Pluggable Authentication Modules (PAM) system is one such approach. PAM was originally developed by Sun, and implementations are

# Read Book Pluggable Authentication Modules

available for Solaris, FreeBSD, and especially Linux, where most PAM development is now centered.

PAM (Pluggable Authentication Modules)  
Pluggable authentication modules are at the core of user authentication in any modern

# Read Book Pluggable Authentication Modules

Linux distribution. 3.1. Why. Back in the good old days of Linux, if a program, such as `su`, `passwd`, `login`, or `xlock`, needed to authenticate a user, it would simply read the necessary information from `/etc/passwd`. If it needed to change the users' password, it would simply edit `/etc/passwd`.
